

# The evolution of serious health-related suffering from 1990 to 2021: an update to The *Lancet* Commission on global access to palliative care and pain relief

Felicia M Knaul, Héctor Arreola-Ornelas\*, Xiaoxiao J Kwete\*, Afsan Bhadelia\*, William E Rosa, Michael Touchton, Oscar Méndez-Carniado, Valentina Vargas Enciso, Tania Pastrana, Joseph R Friedman, Stephen R Connor, Julia Downing, Dean T Jamison, Eric L Krakauer, David Watkins, Renzo Calderon-Anyosa, Rodrigo Garcia-Santisteban, Renu S Nargund, Jim Cleary, Liliana De Lima, Nahla Gafer, Liz Grant, Christian Ntizimira, Pedro E Pérez-Cruz, M R Rajagopal, Dingle Spence, Paul Vila, Lukas Radbruch

## Summary

**Background** The *Lancet* Commission on global access to palliative care and pain relief introduced the concept of serious health-related suffering (SHS) to measure the worldwide dearth of palliative care. This Article provides an extended analysis of SHS from 1990 to 2021 and the corresponding global palliative care need.

**Methods** This Article is the first to apply the SHS 2·0 method published in 2024, incorporating prevalence data from the Global Burden of Diseases, Injuries, and Risk Factors Study to improve non-decedent estimates that account for country-level epidemiological variation; adjusting for non-decedent double counting of HIV/AIDS, cancer, cerebrovascular disease, and dementia; improving the non-decedent estimates for cancer using survivorship data from the Global Cancer Observatory and for HIV/AIDS incorporating access to antiretroviral therapy; differentiating by sex; considering more specific age groups allowing for better estimates, especially in children; and adding endocrine, metabolic, blood, and immune disorders to the health conditions causing SHS. We describe SHS trends globally and within country income groups, differentiating among decedents and non-decedents, by health conditions, sex, and across child and adult age groups.

**Findings** The SHS global burden increased by 74% between 1990 and 2021 to almost 73·5 million individuals, with population growth accounting for only half of that increase. Low-income and middle-income countries (LMICs) accounted for 80% of SHS, with an increase of 83% from 1990 to 2021 compared with a 46% increase in high-income countries (HICs). Between 1990 and 2021, the decedent burden increased by 35%, whereas SHS in non-decedents more than doubled, accounting for 63% of SHS by 2021. The proportion of SHS from communicable diseases declined, especially in LMICs; however, the absolute number stayed relatively stable and even increased from 2019 to 2021 with the start of the COVID-19 pandemic. SHS from non-communicable diseases drastically increased, led by cancer (excluding leukaemia), cardiovascular diseases, and dementia in HICs. HIV/AIDS continued to be a major contributor, accounting for a substantial share of SHS in sub-Saharan Africa. The share of SHS in children decreased from 25% of SHS in 1990 to 14% in 2021 and accounted for 33% of SHS in low-income countries, compared with 2% in HICs. In 2021, SHS in low-income countries was concentrated in female individuals aged 20–49 years (affecting 59% of this population); in HICs, SHS was concentrated in female individuals aged 70 years and older (affecting 54% of this population and probably related to dementia).

**Interpretation** SHS and the associated need for palliative care is a major and persistent but not insurmountable challenge for health systems worldwide. Our findings highlight the urgency to both reduce the avoidable SHS burden through prevention and treatment, and guarantee comprehensive, universal access to palliative care as an equity and health system imperative, especially in LMICs.

## Introduction

Lack of access to palliative care is an opprobrium of global health; it continues to be one of the most neglected and inequitable facets of health systems, despite stark evidence of enormous, preventable global suffering and disparity.<sup>1–3</sup> Indeed, increasing access to palliative care, a core component of universal health coverage, is

essential to achieving Sustainable Development Goal (SDG) 3.8 and continues to be a challenge for health systems of countries throughout the world and at all income levels.<sup>4,5</sup>

In 2017, The *Lancet* Commission<sup>1</sup> on global access to palliative care and pain relief developed a measure of the need for palliative care—serious health-related

## Research in context

### Evidence before this study

The *Lancet* Commission on global access to palliative care and pain relief introduced the concept of serious health-related suffering (SHS)—a novel measure for measuring palliative care need. Using WHO Global Health Estimate data, the Commission reported that over 60 million people had SHS in 2015. The global SHS burden included 25.5 million decedents (45% of all annual deaths) and 35.5 million non-decedents; HIV and cancer accounted for over half of the total cases of SHS. The method developed by the *Lancet* Commission to measure SHS burden has been applied in subsequent studies. For example, in a 2019 projections paper, Sleeman and colleagues estimated that the number of people who die with SHS (decedents) will increase from 26 million in 2016 to 48 million in 2060.<sup>8</sup>

### Added value of this study

This paper provides extended estimates of the evolution of the global SHS burden, extending the previous 2015 point-in-time estimate to a 30-year time series spanning from 1990 to 2021 using the 2021 Global Burden of Diseases, Injuries, and Risk Factors Study data, and incorporating methodological refinements. The extended SHS estimates show that economic development and reduced poverty do not lead to a reduction in SHS and hence, in palliative care requirements. Rather, the results show that SHS increases over time and that low-income countries are facing SHS from communicable diseases as well as

suffering (SHS)—defined as health-related suffering that becomes serious when it cannot be relieved without professional intervention and when it compromises physical, social, spiritual, or emotional functioning.<sup>6,7</sup> The Commission showed that, each year, tens of millions of people live and die with unrelieved SHS. Yet, more than 80% of individuals with SHS reside in low-income and middle-income countries (LMICs) with little or no access to the palliative care that could reduce their suffering burden.<sup>1</sup> Incorporating the SHS data, researchers projected a near doubling of SHS by 2060, concentrated in LMICs and with the largest rise in low-income countries (LICs), where health systems are least prepared.<sup>8</sup> The Commission produced a blueprint for national and global health systems to develop palliative care policies aligned with the 2014 World Health Assembly resolution that declared palliative care as an essential component of comprehensive health coverage.<sup>3,9</sup> SHS was also incorporated in the reporting of the International Narcotics Control Board and WHO.<sup>3,5,10</sup>

This Article advances the Commission's research agenda by strengthening the measurement of SHS as a necessary input to accurately monitor palliative care need and evaluate health system performance.<sup>1,6,11–19</sup> Using data from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD), we present SHS version 2.0—a strengthened method that includes

all other causes. The data show changes in the population groups with SHS in need of palliative care and how patients in low-income and middle-income countries are at risk of not receiving palliative care and having unresolved SHS. Further, our data show the evolution up to 2021 in the health conditions associated with SHS and provide insight into both the populations requiring palliative care and the types of palliative care that they require.

### Implications of all the available evidence

The evidence in this paper highlights the urgency of expanding palliative care access across the lifespan for all patients with SHS. Not doing so risks thwarting efforts to achieve universal health care and advance sustainable development goal 3. Trends to date suggest that the SHS burden from non-communicable diseases will increase across countries at all income levels, shift for all age groups from dying patients (decedents) towards patients with longer survival prognoses (non-decedents), and increase in older adults and decrease in children. Policy must follow suit if this shift occurs, and the scope of palliative care should be intensified and diversified accordingly. Palliative care must respond, but not be limited to, increased survivorship needs for cancer and HIV/AIDS, and simultaneously meet increased demand for various long-term health conditions such as dementia and other degenerative CNS diseases.

information on prevalence, reduces double counting across a subset of diseases, and revises non-decedent estimates for several conditions.<sup>6</sup> Decedents are individuals who died during the year the estimate was calculated; non-decedents are individuals who did not die within that year. We extend the data from the Commission's 2015 point-in-time estimate and develop and present a 30-year time series spanning from 1990 to 2021. Further, we differentiate SHS by sex and more specific age groups and improve the rigour and specificity of the estimates of childhood SHS.

First, we provide a summary of updates to GBD data and methods that are anchored and described in detail in a background methods publication.<sup>6,20</sup> Second, we describe the trends from 1990 to 2021 in the need for palliative care at the global level, by country-income group and by major geographical region, measured as the number of people with SHS and differentiating between decedents and non-decedents. Third, we delve into the differences by sex and age groups, with a focus on trends in child SHS. Finally, we share policy recommendations, limitations of the analysis, and directions for future research.

## Methods

### Improvements to estimation strategy

The SHS 2.0 method incorporates multiple improvements to the strategy that generated the original

estimates published in The *Lancet* Commission on global access to palliative care and pain relief.<sup>6</sup> SHS 2.0 estimates are anchored in the GBD database 2021,<sup>20</sup> which provides country-specific disease mortality, incidence, and prevalence data, enabling a more robust and granular SHS calculation back to 1990, including for smaller age groups and by sex. We present data for 1990, 2000, 2010, and 2021, and provide some insight into the changes between the short period of 2019 (pre COVID-19 pandemic) and 2020 and 2021 (COVID-19 pandemic).

For both adults and children, each GBD subcondition has a corresponding multiplier for decedents and non-decedents, representing the proportion of individuals requiring palliative care. For decedents, the multipliers are applied to all deaths, whereas non-decedent categories are calculated by applying the palliative care multiplier directly to the GBD prevalence data. This method constitutes a major improvement over the previous estimation, for which, due to a lack of prevalence data, SHS was calculated by applying a survivor-to-death ratio to the mortality data. The children's expert group developed child-specific multipliers for each condition to calculate the proportion of children aged 0–19 years needing palliative care.

Informed by recommendations from the Commission report<sup>1</sup> and paediatric palliative care experts, we did a separate estimation strategy for children. This strategy used data from a literature review specific to palliative care needs for children, as well as expert panels of paediatric palliative care professionals from various world regions convened in 2021.<sup>6</sup> The age 15–19 years group was incorporated into the category of children, aligning more closely with accepted medical and socioeconomic definitions of childhood, adolescence, and youth used by UNICEF.<sup>21</sup> The panel added endocrine, metabolic, blood, and immune disorders as a condition for paediatric decedents and non-decedents, and leukaemia, chronic liver diseases, chronic kidney diseases, and preterm birth and birth trauma disorders for non-decedents.

We introduced endocrine, metabolic, blood, and immune disorders for adults, thus improving estimation of diabetes-related SHS and bringing the condition set to 21 (from 20 in the Commission). SHS for non-decedents was added for leukaemia, sickle cell disorders, liver disease, and kidney failure, and we strengthened the estimates of non-decedent SHS for HIV/AIDS, multidrug-resistant and extensively drug-resistant tuberculosis, and cerebrovascular diseases. For HIV/AIDS, we grounded the multiplier on access to antiretroviral therapy, which changed substantially over the study period.<sup>22</sup> For cancer (excluding leukaemia), we refined non-decedent estimation by applying 5-year survival data from the International Agency for Research on Cancer Global Cancer Observatory.<sup>23</sup> We also reduced

the risk of non-decedent double-counting due to comorbidities and the overlap between cancers, dementia, and cerebrovascular diseases, and HIV/AIDS and Kaposi sarcoma.

### Additional procedures

Following the GBD, we divided SHS conditions into: communicable, neonatal, and nutritional diseases (eg, haemorrhagic fevers, tuberculosis, HIV/AIDS, low birthweight and prematurity, birth trauma, malnutrition, and infectious diseases of the CNS); non-communicable diseases including cancer, leukaemia (differentiated from other cancers), dementia, degenerative diseases of the CNS (eg, Parkinson's disease and multiple sclerosis), cerebrovascular diseases, chronic rheumatic heart diseases, cardiomyopathy and heart failure, chronic ischaemic heart diseases, lung diseases, diseases of the liver, renal failure, congenital malformations, atherosclerosis, musculoskeletal disorders, endocrine disorders, metabolic disorders, blood disorders, and immune disorders; and injuries (eg, acute trauma and sequelae such as paralysis). In our analysis, atherosclerosis, ischaemic heart diseases, and non-ischaemic heart diseases are grouped into cardiovascular diseases, and degenerative CNS diseases and dementia into dementia and other degenerative CNS diseases. Following the Commission, we analysed solid cancers and leukaemias separately, because palliative care needs differ.

We calculated 95% uncertainty intervals (UIs) around the number of people with SHS using the upper bound and lower bound values provided by GBD 2021<sup>20</sup> at the country level, by sex, and by age group based on 1000 repeated draws, assuming a normal distribution. For consistency with the approach generally used by GBD, we ran all calculations at the draw level and over 1000 draws, and we took the mean, 2·5th percentile, and 95·7th percentile for the point estimate and UI. The uncertainty in this study therefore reflects the uncertainty in the underlying GBD estimates.

### Country income group classification

To compare country income groups over time, we anchored and reclassified countries using 2021 World Bank categories, because many countries have changed income group since 1990 (eg, China was low-income in 1990, lower-middle-income in 2000, and has been upper-middle-income since 2010; hence in the reclassified data, China is upper-middle-income throughout). This reclassification facilitates comparison of country income groups over time, but masks changes within groups and for specific countries. Hence, we show both the original and reclassified results for 1990, present some non-reclassified data, and include SHS data by geographical region and separately for India and China.

### Results

The global burden of SHS increased 74% between 1990 and 2021. Over 42·2 million people had SHS in 1990, 56·4 million in 2000, over 64·3 million in 2010, almost 71·6 million in 2019, 72·4 million in 2020, and 73·5 million in 2021 (figure 1). The growth rate of SHS was higher between 2020 and 2021 than 2019 and 2020 or in the preceding decade (table, appendix p 4). Population growth accounts for about half of the overall increase.

LMICs account for about 80% of the SHS burden in 2021, and, from 1990 to 2021, SHS increased by 83% in LMICs versus 46% in high-income countries (HICs), using the reclassified data. In 1990, a larger proportion of countries were low-income and accounted for over 55% of total SHS, compared with about 10% in 2021. Between 1990 and 2021, the decedent burden increased by 35%, and the non-decedent burden more than doubled, accounting for 63% of the global SHS burden. In HICs, non-decedents accounted for about 60% of SHS throughout the period, whereas in each group of LMICs there was an increasing amount of non-decedent SHS, reaching over 75% of total SHS in LICs in 2021.

SHS is particularly high in sub-Saharan Africa, which accounted for a higher share of global SHS (26% in 2021) than of the world population (15%), primarily due to HIV/AIDS, and 83% of the SHS is non-decedent. North America, Europe, and central Asia are the only other regions that accounted for a higher proportion of SHS than of the world population, but the difference was small. Between 1990 and 2021, SHS per capita increased in Latin America and the Caribbean, east Asia and the Pacific (including China), Europe, and central Asia, and declined in south Asia (India remained constant) and the Middle East and north Africa (figure 2; appendix p 6).

Globally, in order of magnitude, cancer (excluding leukaemia); cerebrovascular disease; HIV/AIDS; endocrine, metabolic, blood, and immune disorders; and injuries accounted for about 60% of the global SHS burden in 1990 (figure 1). In 2021, in order of magnitude, cancer (excluding leukaemia); HIV/AIDS; cerebrovascular disease; dementia and other degenerative CNS diseases; and endocrine, metabolic, blood, and immune disorders accounted for 74% of the global SHS burden. HIV/AIDS was the lead cause of SHS worldwide in 2000 (24%) and 2010 (21%), but cancer (excluding leukaemia) led in 1990 (20%), 2019 (23%), 2020 (23%), and 2021 (23%). The absolute SHS burden associated with tuberculosis, congenital malformations, inflammatory disease of the CNS, and malnutrition declined from 1990 to 2021,

whereas SHS due to renal failure, disease of the liver, and lung diseases increased.

In LMICs, the proportion of SHS due to communicable, neonatal, and nutritional diseases increased from 1990 to 2000 for decedents and non-decedents, primarily reflecting the increase in HIV/AIDS (figure 3, appendix p 7). The proportion plateaued or declined by 2019 and rose again after the start of the COVID-19 pandemic for non-decedents. The proportion of SHS attributable to non-communicable diseases (NCDs) increased from 2000 onwards for decedents and non-decedents and for all country income groups. Injuries accounted for 3–17% of SHS and were relatively stable across all income groups and all years, for both decedents and non-decedents. For all income groups and throughout the study period, the proportions of NCDs were higher in decedents than in non-decedents, except in LICs in 1990. In LICs, the proportion of non-decedent SHS associated with NCDs was rising, but still below communicable diseases. For decedents, NCDs accounted for over two-thirds of SHS in 2019, 2020, and 2021 for all income groups except LICs (figure 3, appendix p 7).

The distribution of SHS across health conditions varied over time, by country income group, and across decedents and non-decedents (appendix pp 8–9). The concentration of SHS in LICs in 1990 versus 2021 is evident when using the non-reclassified data; the changing distribution of conditions is clearer from the reclassified data. HIV/AIDS represents a large share of SHS in LMICs (LICs: 35% in 1990, 50% in 2000, and 42% in 2021; middle-income countries: about 20% throughout with a large increase in lower-middle-income countries). Cancer (excluding leukaemia) accounted for the largest share of SHS in upper-middle-income countries (27%) and HICs (44%) in 2021. Cancer was a growing cause of SHS for all country income groups, doubling from 8·5 million people in 1990 to 16·6 million in 2021 and increasing from 51% to 61% in LMICs over the study period. Dementia and other degenerative CNS diseases also accounted for a large and increasing share of the SHS burden, increasing from 3·2 million people in 1990 to 8·8 million in 2021, concentrated in upper-middle-income countries and HICs. SHS associated with cerebrovascular disease increased from 5·7 million people in 1990 to 8·9 million in 2021, and the associated burden in LMICs increased from 76% to 85% between 1990 and 2021 (figure 4, table).

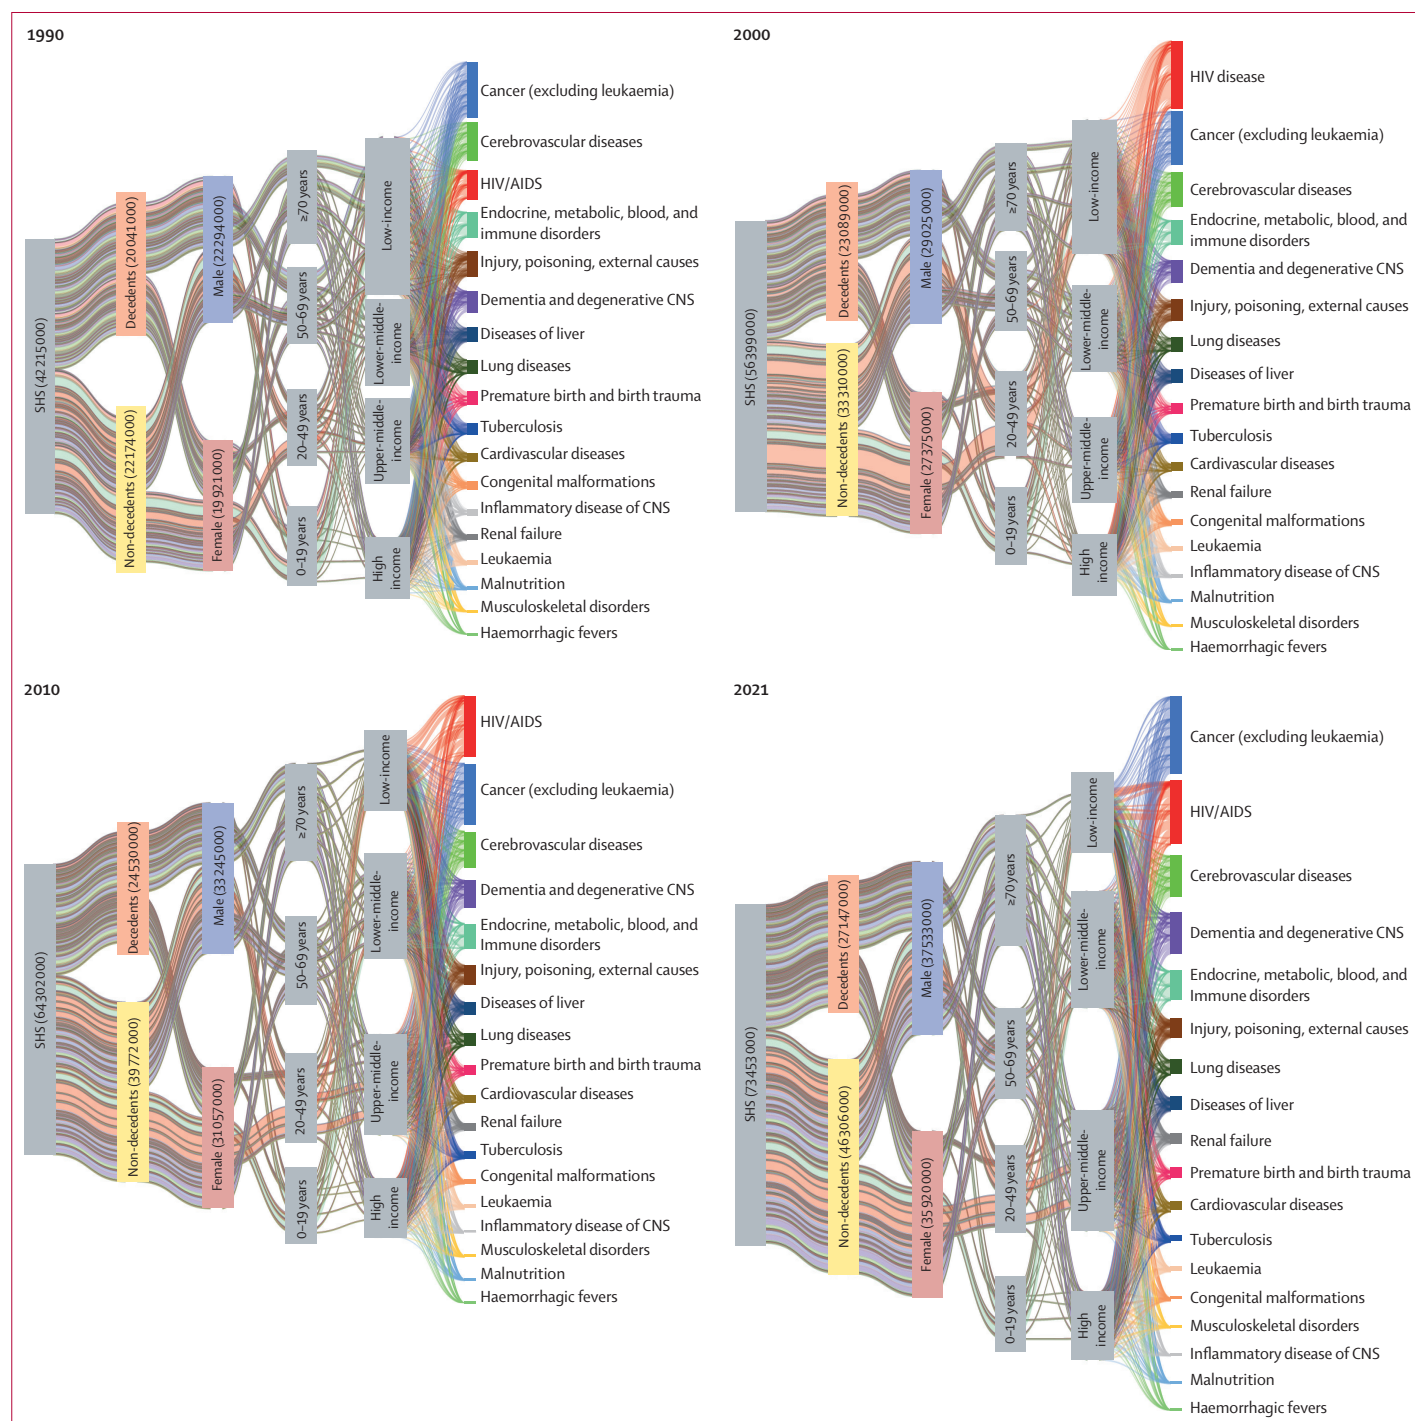

The distribution of decedents and non-decedents with SHS differed across conditions (appendix pp 8–9). Cancer (excluding leukaemia), cerebrovascular disease, tuberculosis, premature birth and birth trauma, and HIV/AIDS were the leading causes of SHS in decedents in LICs in 2021 when compared with cancer (excluding leukaemia), cerebrovascular disease, lung diseases, tuberculosis, and cardiovascular diseases in lower-middle-income countries. In upper-middle-income countries, cancer (excluding leukaemia) was increasing

See Online for appendix

and tuberculosis decreasing. Notably, the proportion of premature birth, birth trauma, and malnutrition among total SHS decedents declined in middle-income countries, but premature birth and birth trauma remained stable at about 10% of all decedents in LICs. Cancer, even excluding

leukaemia, accounted for almost half of decedents with SHS in HICs in both 1990 and 2021. In low-income and lower-middle-income countries, endocrine-related conditions ranked second to HIV among non-decedents in all years, with the exception of lower-middle-income

**Figure 1: Global distribution of SHS health conditions**

Global distribution of SHS health conditions by decedents and non-decedents, sex, age group, and country income group (year-specific, not reclassified) for 1990, 2000, 2010, and 2021. SHS=serious health-related suffering.

SHS=serious health-related suffering.

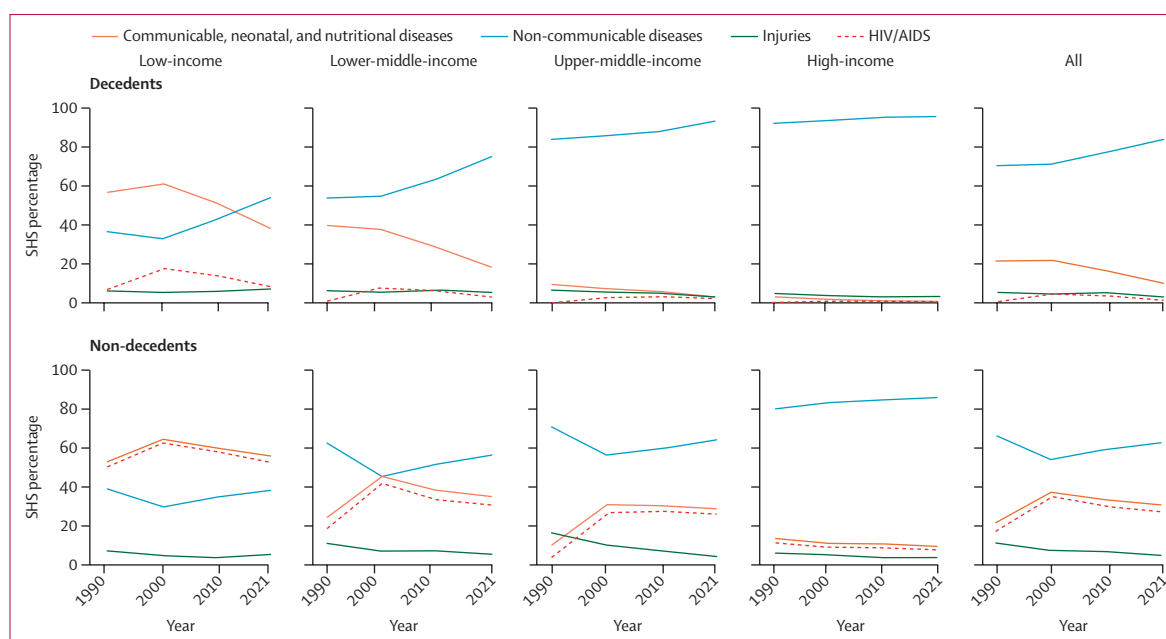

Table: SHS cases 1990–2021, all ages, by health condition (x1000) and country income, ordered by global 2021 SHS

**Figure 2: SHS by country income group and geographical region (decedent vs non-decedent)**

Total SHS (per 1000 population) and rate (per 1000 population) for all ages in 1990, 2000, 2010, and 2021. For the upper half of the graph: 1990–NR=data in 1990 using the income group classification of 1990 and hence, non-reclassified. 1990 (reclassified), 2000 (reclassified), 2010 (reclassified), 2021 (reclassified)=data in those years using the income group classification of 2021 and hence, reclassified. LMICs=low-income and middle-income countries. SHS=serious health-related suffering.

**Figure 3:** SHS (%) grouped by communicable, neonatal, and nutritional diseases (HIV/AIDS included); non-communicable diseases; injury-related conditions; and HIV/AIDS

SHS by country income group and decedent versus non-decedent for 1990, 2000, 2010, and 2021, reclassified by country income group. For more detailed analysis, see the appendix (p 7). SHS=serious health-related suffering.

countries in 1990, in which endocrine-related conditions accounted for 31% of the total non-decedent SHS and was the most common cause.

People living with cancer (excluding leukaemia) were the largest proportion of non-decedents in HICs throughout the study period, whereas people living with HIV/AIDS were the largest proportion of non-decedents across conditions in LMICs in 2021. The number of people living with SHS from HIV/AIDS more than tripled between 1990 and 2021, and over 90% of HIV/AIDS SHS was non-decedent. In LICs, HIV/AIDS comprised over 50% of total non-decedents throughout the study period. For cancer, the ratio of decedent to non-decedent SHS declined globally from 1.4 in 1990 to 1.0 in 2021. SHS for dementia and other degenerative CNS diseases was more common in non-decedents than decedents. For dementia and other degenerative CNS diseases, the percentage of non-decedents among total SHS remained at 78% throughout the study period.

The distribution of SHS overall and of decedents and non-decedents is shifting from children towards older age groups over time (decrease in SHS among children from 25% to 14% of SHS from 1990 to 2021; appendix pp 10–12). Using reclassified data, children comprised 42% of SHS in 1990 in LICs compared with 33% in 2021, 40% of SHS in 1990 in lower-middle-income countries compared with 25% in 2021, 17% of SHS in 1990 in upper-middle-income countries compared with 5% in 2021, and 5% of SHS in 1990 in HICs compared with 2% in 2021. Non-decedent SHS in LICs was still concentrated in children and in adults aged 20–49 years

in 2021, but the shift to older age groups has begun in lower-middle-income countries and has advanced in upper-middle-income countries and HICs. For children, the shift to non-decedent SHS is marked: in LICs the non-decedents to decedents ratio was 1.4 in 1990 and 3.7 in 2021, in lower-middle-income countries it was 1.6 in 1990 and 4.7 in 2021, and in upper-middle-income countries it was 1.6 in 1990 and 5.7 in 2021.

The shift towards older populations over time and by income group is also seen when the data are differentiated by sex (figure 5; appendix pp 10–11). For those aged 0–19 years, males accounted for more SHS than females across all income groups and years, except for LICs in 1990 and 2000, when SHS among females was slightly higher than in males. For those aged 20–49 years, females in LICs accounted for more SHS than males in all years for those aged 20–49 years. In 2021, cancers (excluding leukaemia) accounted for a larger share of SHS in females than males aged 20–49 years in all country income groups. Also in 2021, SHS in low-income countries was concentrated in female individuals aged 20–49 years (affecting 59% of this population); in HICs, SHS was concentrated in female individuals aged 70 years and older (affecting 54% of this population and probably related to dementia). HIV/AIDS-related SHS is higher for females in all age groups in all LMICs for the years 2019, 2020, and 2021, but higher for males in HICs in all age groups for those years. For all years in our data, dementia and other degenerative CNS disease-associated SHS was higher for females than for males in all income groups for age groups 50–69 years and 70 years and

## Discussion

Among the most salient change in SHS is the reduction in the number of children needing palliative care for communicable and poverty-related diseases. Across country income groups, the proportion of SHS accounted for by children has declined from 25% in 1990 to 14% in 2021. Yet, increasing availability of life-saving technology for children born premature and support for children living with disability and chronic disease will increase long-term survivorship, hence the burden of non-decedent, childhood SHS and corresponding palliative care needs.<sup>35–38</sup> Further, the burden of SHS in children is increasingly and markedly concentrated in low-income settings where palliative care is scarce.<sup>3</sup>

The number of people living in poverty declined substantially between 1990 and 2019, paralleling the distribution of SHS: 30 years ago, most people with SHS lived in LICs, whereas today, the majority live in upper-middle-income countries.<sup>39</sup> Sub-Saharan Africa continues to hold a disproportionately large share of SHS relative to

**Figure 5: Total SHS (x1000) by health condition, age, and sex**

SHS reclassified by country income region; 1990, 2000, 2010, 2019, and 2021 (scaled). SHS=serious health-related suffering.

its population size due to the high burden of HIV/AIDS; this difference has probably been exacerbated by the increased global poverty caused by the COVID-19 pandemic.<sup>40-43</sup> Further, global inequality means that many low-income people reside in higher-income countries and face unresolved SHS, which can only be measured through subnational analysis.

SHS from HIV/AIDS is among the top five SHS conditions, even in HICs. Although HIV/AIDS is still the leading contributor to SHS in LMICs, where palliative care often emerged from the need to care for patients with AIDS, infectious disease-related SHS accounted for less than half of overall SHS in 2019, indicating a shift of palliative care needs from infectious to non-infectious

diseases.<sup>44</sup> Indeed, changes in the number of people living and dying with HIV/AIDS account for much of the overall change in SHS, both across country income groups and between decedents and non-decedents. Yet, palliative care needs are rapidly changing, as, with growing access to ART, HIV/AIDS has transformed from a fatal to a chronic condition.<sup>45-47</sup> This change means that HIV/AIDS-associated SHS involves fewer days per year of suffering, and hence palliative care needs are reduced or even eliminated for some patients on maintenance therapy.<sup>48,49</sup> Indeed, in HICs, HIV/AIDS care is now disengaged from palliative care and people with HIV/AIDS might find care difficult to access.<sup>49,50</sup> Further, advanced HIV/AIDS and survivorship in all countries

**Panel: Data limitations and ongoing and future work**

- Headcounts based on the assumption that patients with even 1 day of serious health-related suffering (SHS) should have access to adequate palliative care provide limited insight into the nature of palliative care need.<sup>24</sup> Data on prevalence and duration of symptoms and days of palliative care encounters at each level of care are essential to better determine the need for medical equipment, social support, human resources, and medicines.
- Fixed multipliers determine the proportion of deaths and prevalent cases that require palliative care and do not vary over time or place (except for HIV/AIDS on access to antiretroviral therapy and for cancer survivorship). Future work should develop more flexible, country-specific multipliers and account for the evolution of medical science.
- Country income classification according to the World Bank—low-income, lower-middle-income, upper-middle-income, or high-income—while useful for comparison does not allow for within-country analysis and mask inequity and differences in palliative care need for underserved populations, including in high-income countries. Future research should be subnational and focus on vulnerable groups.
- Estimates rely on published data and expert opinion from a small group of palliative care providers, and although special effort was made in SHS 2.0 to ensure geographical diversity in expert groups, more specificity in knowledge of health conditions is required. Also, literature, particularly on less common SHS conditions, is scant. Condition-specific and region-specific expert group analysis, as well as primary data from patients and caregivers, are required to resolve limitations. Disease-specific data collection was piloted for breast cancer,<sup>24</sup> but developing SHS 3.0 is seriously resource-constrained, reflecting the overall neglect of palliative care as a global health and equity priority.
- The COVID-19 pandemic is not adequately reflected, as although data reach 2021, this only touches on the unprecedented physical and psychosocial suffering of the pandemic, both from the virus and the lockdowns that restricted access to health care. SHS should be expanded to encompass the new vectors of suffering and palliative care need that are emerging post-2021. The additional burden brought by COVID-19 could exceed 50 million people, assuming all deaths (6 million) and 10% of the 458 million survivors have SHS.<sup>25</sup> Longer-term effects (reduced access to primary care, screening, and treatment) for other SHS conditions will generate an additional spike, as will the little-understood psychosocial effects of mass global grief and bereavement, including on health-care providers. As evidence becomes available, it will be important to iteratively and comprehensively evaluate COVID-19-related palliative care needs.
- Social, spiritual, and financial dimensions of SHS and vectors of suffering are excluded, as SHS exclusively explores physical and psychological distress. Social, spiritual, and financial dimensions are especially salient in extreme poverty and humanitarian crises, including migration, refugee crises, political violence, armed conflict, climate catastrophes, and other natural catastrophes. The alleviation of social and spiritual suffering is foundational to palliative care, which, alongside financial protection, needs to be incorporated into SHS and health systems performance assessments.
- Suffering as a health outcome is not measured, generating a priority-setting gap whereby the alleviation of suffering is undervalued. Understanding the full value of suffering alleviation to patients and their loved ones is required to inform priority-setting and address the lack of palliative care worldwide. Findings show that patients and informal caregivers assign high value to suffering alleviation, at times prioritising it above treatment.<sup>26,27</sup> Yet, the dearth of research, especially from low-income and middle-income countries,<sup>28–34</sup> necessitates a systematic effort to bridge this knowledge gap to develop a patient-weighted, preference-based, multi-attribute utility measure of suffering averted to improve resource allocation across the care continuum, including palliative care.<sup>1,27</sup>
- Uncertainty analysis is limited as we assumed a normal distribution for the generation of 1000 draws from underlying The Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) estimates, which might imperfectly represent the true modelling distribution. Furthermore, our uncertainty intervals only reflect uncertainty from the GBD estimates, and do not include uncertainty in expert-defined parameters, which remains an important area for future work.
- Coding the 21 SHS conditions relied on the expert panel convened by the *Lancet* Commission to identify the conditions and sub-conditions that generate need for palliative care. GBD codes were identified based on matching names of the SHS subconditions, and there are small variations in how GBD 2021 assigns ICD-10 codes to some subconditions that do not exactly correspond to the ICD-10 codes used to describe the 21 SHS conditions. Future work will include an update of conditions and subconditions.

will be increasingly accompanied by vulnerability to various NCDs.<sup>51</sup>

Too often, palliative care provision and financing is linked or even limited to cancer, yet our data show that only 25% of SHS stems from cancer (including leukaemia). Although increasing access to palliative care

to meet the growing burden of cancer is essential,<sup>52</sup> this finding also highlights the need to decouple palliative care from cancer and guarantee access for other communicable diseases, NCDs, and injury. For example, for dementia and other degenerative CNS diseases, even in HICs the need for palliative care for patients and their

families and caregivers often goes unrecognised.<sup>53–58</sup> In addition, unintentional and intentional injury in children and adults generates need for palliative care to mitigate the effect of both physical and psychological trauma. The focus on health conditions that generate the greatest burden of SHS biases coverage (in quality and financing) and diverts attention from the many other causes that are less prevalent yet require specialised palliative care services. Because some health conditions are more common or even unique to the lowest-income countries and populations, palliative care planning must take a broad approach to health conditions to avoid bolstering rather than mitigating inequities.

The trajectory of the SHS burden will depend on how health systems invest in reducing and managing the disease burden. SHS, and hence the palliative care that is required to alleviate it, is attributable to both conditions associated with suffering that cannot be prevented with access to more and better prevention and treatment, and suffering associated with morbidity and mortality from conditions that could have been prevented with adequate, appropriate medical and public health interventions. The first component of SHS is inevitable or refractory, and is prone to grow as countries and their health systems develop, whereas the second component is avoidable, should shrink, and is responsive to more and better investment in health and the social determinants of health. In LMICs, a large part of the SHS burden continues to be associated with illnesses that are preventable and treatable. In countries without adequate health care resources, higher percentages of patients will access health care only in advanced stages of the disease trajectory, with more suffering throughout the disease. Often, patients will be beyond cure or rehabilitation, leading to SHS that could have been avoided with more preventive or curative health care. As an example, having only one radiotherapy machine in an African lower-middle-income country leads to long waiting lists, with some cancer patients dying on the waiting list and others progressing towards incurable cancer. Avoidable deaths are linked with avoidable SHS and the refractory component is growing rapidly, generating a double burden of palliative care need. In HICs, the component of avoidable SHS is much smaller, but even with optimal health care, some incurable illnesses will progress and cause SHS. For example, a substantial percentage of patients with breast cancer will develop metastatic disease, with an average survival time of 5 years in HICs, causing (inevitable) SHS that requires treatment.<sup>24</sup>

The quest to achieve universal access to palliative care should not be used to mask underperforming health systems that fail to prevent or treat diseases and, by failing to do so, result in an excess burden of SHS. Palliative care should never substitute but rather complement disease management, and it is crucial that health systems mitigate avoidable mortality and build robust palliative care programmes for the population

with refractory SHS. It is a failure of health systems to carry an excess SHS burden, be it due to the lack of access to palliative care services for health conditions that are responsive to palliative care (eg, inevitable SHS from incurable cancers), or to the refractory or avoidable components due to a failure to prevent and treat health conditions (eg, malnutrition or tuberculosis).

Our results show not only the magnitude of SHS, but also the opportunities to alleviate that burden if decision makers allocated more and more effective health-care resources to palliative care through multilevel provision of palliative care encompassing a general level in primary care and specialists for complex cases.<sup>7</sup> Alleviation and, if possible, prevention of suffering is not only a moral obligation, but also necessary to reduce the hidden costs of suffering,<sup>24</sup> such as productivity loss, impoverishment from health-care spending, and exacerbated gender inequities, whereby women and girls assume most uncompensated caregiving.<sup>59</sup>

The future need for palliative care depends partly on the willingness of global political and financial leaders and institutions to eliminate social determinants of illness and to promote equity in access to disease prevention, diagnosis, and treatment. As health systems and ministries work to integrate the recommendations of The *Lancet* Commission on palliative care and pain relief and the SDGs to ensure universal palliative care access, it is essential to ensure that health and care sectors strategically allocate health resources and mitigate suffering throughout the life course and across the illness–wellness continuum, particularly in LMICs, which shoulder a disproportionate burden of SHS.

#### Contributors

FMK, LR, XJK, HA-O, and AB contributed to the conceptualisation and design. FMK wrote the first draft with inputs from HA-O, LR, XJK, AB, and WER and finalised the text. LR, WER, JD, and ELK anchored the analyses of palliative care need from a clinical perspective. SC, JD, DTJ, DW, and JF provided methodological and statistics expertise. ELK, JC, LDL, JD, LG, CN, NG, TP, PEP-C, MRR, and DS contributed to data collection. HA-O, XJK, AB, OM-C, and RC-A conducted data analyses. WER, RC-A, MT, RSN, RG-S, VVE, and PV contributed to data presentation, bibliographic review, and writing. MT, WER, LR, HA-O, XJK, AB, JF, and VVE worked with FMK to prepare reviewer responses. All authors contributed to data interpretation and text inputs into the final draft. All authors had full access to all the data in the study and had final responsibility for the decision to submit for publication.

#### Declaration of interests

FMK reports research grants to Tómatelo a Pecho from the University of Cambridge (funder: Breast Cancer Now), Merck Sharp & Dohme Comercializadora, and Avon Cosmetics; research grants to the University of Miami on palliative care from the UK Medical Research Council and US Cancer Pain Relief Committee; a research grant from EMD Serono; gift funding from the ABC Global Alliance to the University of Miami; personal consulting fees from Merck KGaA–EMD Serono and Tecnológico de Monterrey; leadership positions or fiduciary roles in other boards, societies, committees, or advocacy groups as the Founding President of Tómatelo a Pecho, as Senior Economist (unpaid) at the Mexican Health Foundation, and as a member (unpaid) of the Board of Directors of the International Association of Hospice and Palliative Care. HA-O reports consulting fees collected through the University of Miami from Merck KGaA. XJK reports consulting fees for part of the submitted work from the University of Miami Institute for the Advanced Study of

the Americas; consulting fees through a research grant from the Medical Research Council to the University of Edinburgh outside the submitted work; and additional consulting fees as grants from Merck KGaA–EMD Serono, given through the University of Miami Institute for Advanced Study of the Americas. AB reports consulting fees from the University of Miami Institute for the Advanced Study of the Americas for part of the submitted work; receipt of the Fulbright US Scholar Teaching and Research Award from the Bureau of Educational and Cultural Affairs, US Department of State outside of submitted work; consulting fees through a research grant from the Medical Research Council to the University of Edinburgh outside the submitted work; and Honoraria from Memorial Sloan Kettering for presentation outside the submitted work. WER reports receipt of the National Cancer Institute–National Institute of Health Comprehensive Cancer Center Award P30CA008748. TP reports payment and honoraria from RWTH Aachen University, City Cancer Challenge; support for attending meetings and travel from RWTH Aachen University and International Association for Hospice & Palliative Care; leadership positions or fiduciary roles in other boards, societies, committees, or advocacy groups as a Research Advisor at IAHP, co-chair at the Reference Group Primary Palliative Care, and is a board member at RG Public Health. SC reports salaried part-time employment at the Worldwide Hospice Palliative Care Alliance as part of support for the present manuscript; book royalties from Routledge Publishing; leadership positions or fiduciary roles in other boards, societies, committees, or advocacy groups as a board member (non-paid) of the International Children's Palliative Care Network, as a board member (non-paid) of the Elisabeth Kubler-Ross Foundation, as a Scientific Advisory Board member (non-paid) of Mt Sinai Hospital, National Palliative Care Research Center, as a member of the Editorial Board (non-paid) of the *Journal of Pain & Symptom Management*, as a board member (non-paid) of Ehospace, and as a board member (non-paid) of Public Health & Palliative Care International. JC reports a leadership position or fiduciary roles in other boards, societies, committees, or advocacy groups as a trustee of the World Hospice and Palliative Care Alliance. LR reports other financial or non-financial interests as Chair of the Board of Directors of the International Association for Hospice and Palliative Care. All other authors declare no competing interests.

#### Data sharing

The data used in this research will be available upon publication at the Harvard Dataverse (<https://dataverse.harvard.edu/dataverse/IAHPC>) as well as the Instituto Tecnológico de Monterrey's website. The complete dataset will be made publicly available and open access alongside the publication of this research paper.

#### Acknowledgments

We are grateful to The *Lancet* Commission on palliative care and pain relief study group and acknowledge contributors in the *Lancet* Commission report to an earlier iteration of this work. We would also like to thank the palliative care specialists who contributed to expert panels (Julia Ambler, Nickhill Bhakta, Megan Doherty, Richard Hain, Rut Kima, and Marianne Phillips) and related Delphi processes for the *Lancet* Commission and subsequent paediatric-specific expert reviews for SHS 2.0. We also want to thank the individuals who have supported us throughout the process and contributed their time and expertise—Sonia Xochitl Ortega Alanis and Gerardo Pérez Castillo. We take this opportunity to recognise and acknowledge a leading voice behind this overall work—Paul Farmer—who served as former co-Chair of the *Lancet* Commission and passed away in February, 2022. His notable insights and guidance were crucial to bringing the global inequity in palliative care to light. We thank Kathy Foley for her various inputs to the *Lancet* Commission and beyond to help make this work a reality. We also thank various administrative staff across the organisations represented by the coauthors who have supported coordination and communication to help bring this manuscript to fruition. Further, we express our gratitude to anyone who contributed in any way to the work presented and whom we may have inadvertently missed. We dedicate this work to individuals living with SHS worldwide, many of whom are not in a position to advocate for expanded access to palliative care and pain relief. We acknowledge support from the University of Miami, US Cancer Pain Relief, Medical Research Council via the University of Edinburgh, and an anonymous donor who contributed through GDS for this work. WER is

partially funded by National Institute of Health–National Cancer Institute Comprehensive Cancer Support Grant award P30 CA008748.
